

DCF VALUATION OF INDIAN RENEWABLE ENERGY IPPs

A bottom-up Free Cash Flow to Firm (FCFF) analysis of Adani Green Energy, NTPC Green Energy, and ACME Solar Holdings

Prepared by: Raghav Rao (Rao)
B.Tech, Mechanical Engineering — IIT Ropar
Self-directed project, undertaken with faculty guidance

Market data as of early August 2026 · Figures in Rs. Crores unless noted

- 7. Hypothesis Test & Conclusion**
- 8. Key Drivers & Limitations**

1. Why These Companies — Selection Rationale

This project tests a single hypothesis: are current market valuations of listed Indian renewable energy Independent Power Producers (IPPs) pricing in capacity-addition and margin assumptions more aggressive than a bottom-up, company-specific discounted cash flow (DCF) can support? Three companies were selected to test this across different risk profiles within the same sector, rather than relying on a single name.

Adani Green Energy — Primary Company

Adani Green is the primary company in this study. It is the largest pure-play listed renewable IPP in India (roughly Rs 2.5 lakh crore market capitalisation), carries the most aggressive capacity-addition pipeline in the sector (a 50 GW target by 2030), and attracts by far the highest analyst and media attention among Indian renewable IPPs. That combination makes it the clearest test case for the growth-narrative-versus-fundamentals question this project asks — if the market-price-to-intrinsic-value gap exists anywhere in the sector, it should be most visible here.

NTPC Green Energy — Peer

NTPC Green was chosen as a peer with a fundamentally different risk profile: a listed, PSU-backed IPP with a lower cost of capital from government backing, a much smaller and newer asset base (incorporated in 2022), and a more conservative build-out pace. It gives the comparison set a lower-risk counterpoint, testing whether the market prices sponsor quality differently across otherwise similar renewable-capacity businesses.

ACME Solar Holdings — Peer

ACME Solar was chosen as the second peer: a smaller, solar-focused pure-play with a longer listed history (financial data back to FY20) than the other two. That longer run gives a useful view of how tariff realisation and margins behave through a full capacity-build cycle — including a period of declining revenue between FY20 and FY23 — which neither Adani Green nor NTPC Green's shorter public histories can provide.

Together, the three companies span the largest and most-followed name in the sector (Adani Green), a PSU-backed lower-risk listing (NTPC Green), and a smaller, less-covered pure-play (ACME Solar) — letting the project check whether any overvaluation finding is sector-wide or concentrated in the highest-profile names.

2. Capex Formation — Deriving the Cost-per-MW Input

The FCFF model needs a forward capex estimate for each company's announced capacity pipeline. Rather than extrapolating top-down from historical capex growth, a bottom-up cost-per-MW figure was derived for each company from its own disclosed capex and capacity-addition data, then applied to that company's own pipeline.

2.1 Adani Green Energy — directly disclosed, no proxy needed

Adani Green discloses an explicit “Capex Incurred” figure each year alongside annual capacity additions in GW, giving a clean, directly-stated cost-per-MW.

Year	Capacity Added (MW)	Capex Incurred (Rs cr)	Cost per MW (Rs cr)
FY25	3,300	28,366	8.59
FY26	5,100	30,365	5.95

Cost per MW fell by roughly a third in one year, consistent with the company's commentary on large-scale, single-location execution at Khavda and backward-integrated module/turbine sourcing. The FY26 rate (Rs 5.95 cr/MW) is carried forward as it reflects current technology and procurement costs. Applied to the 50 GW-by-2030 target (~30.2 GW to be added over ~4.5 years, or ~6.7 GW/year), this implies forward capex of roughly **Rs 39,900 cr/year** at the FY26 rate (vs ~Rs 57,600 cr/year at the more conservative FY25 rate).

2.2 NTPC Green Energy — proxied via Cash Used in Investing Activities

NTPC Green's investor presentation does not disclose an explicit capex-incurred line the way Adani Green does. Cash Used in Investing Activities is used as a proxy against disclosed annual capacity additions — a broader line than pure capex, since it can include loans to subsidiaries/JVs, investments, and deposits, and can be reduced by stake-sale proceeds not visible at this level of detail.

Year	Capacity Added (MW)	Cash Used in Investing (Rs cr)	Cost per MW, proxy (Rs cr)
FY25	2,977	17,793	5.98
FY26	4,174	12,117	2.90

The FY26 figure (Rs 2.90 cr/MW) is markedly lower than both Adani Green's rate and NTPC Green's own FY25 figure — plausibly reflecting PSU-backed cheaper land and financing, but also plausibly understated by netting effects in the cash-flow statement. FY25's rate (Rs 5.98 cr/MW) is treated as the safer figure for forward estimates. Applied to the 16,318 MW Contracted & Awarded pipeline, this implies a forward capex requirement of roughly **Rs 97,600 cr** for the already-contracted book (a range of ~Rs 47,000–98,000 cr across the two proxy rates is the more defensible way to present this, given the proxying uncertainty).

2.3 ACME Solar Holdings — cost-per-MW could not be independently derived (data gap)

This is a genuine gap in the source material, and is flagged explicitly here rather than papered over. Unlike the other two companies, ACME Solar's available data is limited to a single point-in-time snapshot from its Q1 FY27 results-highlights slide — not a multi-year capacity-addition and capex series. A company-specific cost-per-MW could not be reliably computed from what has been sourced so far.

Metric	Value (as of Q1 FY27)
Operational Contracted Capacity	2,990 MW
Under-Construction Contracted Capacity	5,080 MW

Total Portfolio Contracted Capacity	8,070 MW
Cumulative BESS Commissioned	~3.62 GWh

Proxy used in the model: in the absence of a company-specific figure, the ACME Solar FCFF model uses **Rs 5.97 cr/MW** — the average of Adani Green's FY26 rate (5.95) and NTPC Green's FY25 rate (5.98) — as a sector benchmark. This is the single most significant data gap in the model set and directly affects ACME Solar's forward capex line, and therefore its FCFF and valuation.

What would close this gap:

- A full ACME Solar investor presentation (not just the results-highlights cover slide) with a year-wise capacity-addition chart, comparable to Adani Green's or NTPC Green's portfolio slides.
- An explicit capex-incurred figure, or at minimum enough cash-flow history to compute a proxy the way NTPC Green's was derived.
- Until sourced, this is flagged to the professor as a known, explainable gap at this stage of the project rather than a modelling error.

3. Introduction to the FCFF Model

Free Cash Flow to Firm (FCFF) is the cash generated by a company's core operations that is available to *all* capital providers — both equity and debt holders — before any financing decisions. Unlike Free Cash Flow to Equity, FCFF is capital-structure-neutral, which makes it the right measure for valuing the whole enterprise (Enterprise Value) rather than just the equity slice, and is well suited to comparing companies with very different debt levels — a real consideration here, given Adani Green's 5.2x–7.4x Debt/Equity versus NTPC Green's 1.1x–2.2x.

3.1 The FCFF build, line by line

Line	Definition used in this model
Revenue	Base-year run-rate revenue grown using operational capacity added each year, scaled by a Revenue Ramp Factor for capacity added mid-year.
EBIT	Revenue × Operating Margin (OPM). OPM is held constant at each company's most recent actual rate.
Less: Tax	EBIT × Effective Tax Rate. Adani Green uses a normalised rate rather than its unusually low FY26 actual, which reflects a temporary accelerated-depreciation shelter.
NOPAT	Net Operating Profit After Tax = EBIT – Tax. The starting point for FCFF.
Add: D&A	Depreciation & Amortisation, added back as a non-cash charge. Modelled as a fixed % of prior-year Net Fixed Assets.
Less: Capex	Capacity added in the year × Cost per MW (see Section 2), i.e. the bottom-up capex build.
Less: Chg. in Working Capital	Modelled as a fixed % of the year-on-year change in revenue (placeholder assumption, common to all three models).
FCFF	= NOPAT + D&A – Capex – Chg. in Working Capital. The cash flow that is discounted back to present value.

3.2 Discounting and terminal value

Each explicit-period FCFF (FY27–FY35, a nine-year window) is discounted back to present value using the company's **Weighted Average Cost of Capital (WACC)**, built from a CAPM cost of equity (risk-free rate + beta × India equity risk premium) and an after-tax cost of debt, weighted by market-value equity and debt. Beyond FY35, cash flows are assumed to grow at a constant **Terminal Growth Rate (g)** of 5% — roughly long-run nominal GDP growth — and are capitalised into a single Terminal Value using the Gordon Growth formula:

$$\text{Terminal Value (at end of FY35)} = \text{FCFF}_{\text{FY36}} \div (\text{WACC} - g)$$

Enterprise Value = Sum of PV of explicit-period FCFF (FY27–FY35) + PV of Terminal Value. Equity Value is then Enterprise Value minus Net Debt, and Intrinsic Value per Share is Equity Value divided by shares outstanding — the figure compared against each company's current market price.

3.3 Why Terminal Value dominates

Across all three models, Terminal Value accounts for the large majority of Enterprise Value — roughly 3x the explicit-period PV for NTPC Green, for example. This is expected for capital-intensive, front-loaded-capex businesses where cash flow only turns solidly positive once the heavy build-out phase tapers off after FY30. It also means the valuation conclusion is most sensitive to two assumptions: WACC and terminal growth (g) — a point returned to in Section 8.

4. Company Assumptions & FCFF Forecasts

This section documents the full assumption set behind each company's FCFF model, followed by the resulting nine-year forecast (FY27–FY35) and Enterprise Value build. Detailed year-by-year tables are presented in landscape format in the pages following each company's assumptions for readability.

4.1 Adani Green Energy

Base year: FY26 actuals. Operational capacity of 19,294 MW as of the FY26 investor presentation is grown to the company's own 50,000 MW 2030 target, then at a slower 3,000 MW/year terminal pace through FY35.

Assumption	Value	Basis / Source
Base capacity (FY26)	19,294 MW	AGEL Investor Presentation, May 2026, asset-level total
Target capacity (FY30)	50,000 MW	Company's own 2030E target
Terminal growth (FY31–35)	3,000 MW/yr	Placeholder for post-2030 slower phase
Cost per MW	Rs 5.95 cr	FY26 rate, directly disclosed (Section 2.1)
Base revenue (FY26)	Rs 11,602 cr	AGEL Investor Presentation — Revenue from Power Supply
Revenue ramp factor	0.85	New capacity generates ~85% of a full year's proportional revenue in year added
Operating margin (EBITDA/Rev)	91.2%	AGEL FY26 EBITDA margin, actual
Effective tax rate	15% (normalised)	FY26 actual (~1–10%) reflects an accelerated-depreciation shelter, not sustainable
Base net fixed assets (FY26)	Rs 1,21,168 cr	AGEL Balance Sheet FY26, incl. CWIP
D&A (% of prior NFA)	3.0%	Derived from FY26 depreciation / FY26 net fixed assets
Chg. in working capital (% of Rev chg.)	5%	Placeholder assumption, common across all three models
WACC	10.0%	Placeholder — pending full CAPM computation (Rf, re-levered beta, India ERP, cost of debt)
Terminal growth rate (g)	5.0%	Approx. long-run nominal GDP growth

Applying these assumptions, FCFF stays negative through FY30 as the heavy capex phase to reach 50 GW outweighs operating cash flow, turning solidly positive from FY31 as the build-out pace slows to the terminal 3,000 MW/year rate.

Valuation Summary	Rs. Crores
Sum of PV of FCFF (Explicit Period, FY27–FY35)	(40,393)
Terminal Value (Gordon Growth, end of FY35)	3,62,548
PV of Terminal Value	1,53,756
Enterprise Value — Base Case	1,13,363

Adani Green Energy — FCFF Forecast, FY27–FY35 (Rs. Crores)

PV of FCFF	—	-27,455	-21,504	-16,510	-12,325	7,504	7,567	7,547	7,461	7,322

4.2 NTPC Green Energy

Base year: FY26, with revenue re-based to the Q1 FY27 annualised run-rate to correct for the fact that NTPC Green nearly doubled capacity mid-year (5,902 to 10,076 MW), which would otherwise understate current run-rate revenue.

Assumption	Value	Basis / Source
Base capacity (30-Jun-26)	10,671 MW	NGEL Q1 FY27 Investor Presentation, consolidated operational capacity
Target capacity (FY30)	26,989 MW	Derived: Operational + Contracted & Awarded per NGEL portfolio slide
Terminal growth (FY31–35)	700 MW/yr	Draws down the 3,424 MW MOU-stage pipeline over the terminal period
Cost per MW	Rs 5.98 cr	FY25 proxy rate — safer than the likely-understated FY26 proxy (Section 2.2)
Base revenue (annualised Q1 FY27)	Rs 4,428 cr	Q1 FY27 revenue Rs 1,107 cr × 4, replacing the FY26 full-year average
Revenue ramp factor	0.85	Same basis as the Adani Green model, for comparability
Operating margin (OPM)	87.0%	Screener.in, FY26 actual
Effective tax rate	24%	Screener.in, FY26 actual — used as-is, no normalisation needed
Base net fixed assets (FY26)	Rs 53,395 cr	Screener.in Balance Sheet FY26, incl. CWIP
D&A (% of prior NFA)	3.0%	Derived from FY26 depreciation / FY25 net fixed assets
Chg. in working capital (% of Rev chg.)	5%	Placeholder assumption, common across all three models
WACC	10.6%	Rf 6.8% + Beta 0.8 × India ERP 7.31% = CoE 12.65%; after-tax CoD 5.53%; ~71/29 E/D weights
Terminal growth rate (g)	5.0%	Approx. long-run nominal GDP growth

NTPC Green's FCFF is negative for all four years of the explicit ramp phase (FY27–FY30) and by a wider margin relative to its revenue base than the other two companies — the 16,318 MW Contracted & Awarded pipeline represents a very large capex commitment against a still-small FY26 revenue base of Rs 2,858 cr.

Valuation Summary	Rs. Crores
Sum of PV of FCFF (Explicit Period, FY27–FY35)	(35,326)
Terminal Value (Gordon Growth, end of FY35)	1,36,183
PV of Terminal Value	54,995
Enterprise Value — Base Case	19,670

NTPC Green Energy — FCFF Forecast, FY27–FY35 (Rs. Crores)

4.3 ACME Solar Holdings

Base year revenue is annualised from the Q1 FY27 run-rate for the same reason as NTPC Green — ACME Solar's capacity and revenue base is still actively ramping. As flagged in Section 2.3, the cost-per-MW input is a sector-average proxy rather than a company-specific figure, which is the largest single data-quality caveat in this model.

Assumption	Value	Basis / Source
Base capacity (Q1 FY27)	2,990 MW	ACME Solar Q1 FY27 Results Highlights — Operational Contracted Capacity
Target capacity (FY30)	8,070 MW	Total Portfolio Contracted Capacity (Operational + Under Construction)
Terminal growth (FY31–35)	300 MW/yr	Assumption — smaller scale than the other two; refine once fuller pipeline data is disclosed
Cost per MW	Rs 5.97 cr (PROXY)	No ACME-specific rate available — average of Adani Green FY26 (5.95) and NTPC Green FY25 (5.98)
Base revenue (annualised Q1 FY27)	Rs 3,816 cr	Q1 FY27 revenue Rs 954 cr × 4, annualised, replacing the FY26 full-year average
Revenue ramp factor	0.85	Same basis as the other two company models, for comparability
Operating margin (OPM)	87.1%	Q1 FY27 EBITDA (Rs 831 cr) / Revenue (Rs 954 cr)
Effective tax rate	26%	Screener.in, FY26 actual
Base net fixed assets (FY26)	Rs 20,090 cr	Screener.in Balance Sheet FY26, Fixed Assets + CWIP
D&A (% of prior NFA)	3.5%	Derived from FY26 depreciation / FY25 net fixed assets, rounded
Chg. in working capital (% of Rev chg.)	5%	Placeholder assumption, common across all three models
WACC	10.3%	Rf 6.8% + Beta 1.0 × India ERP 7.31% = CoE 14.1%; after-tax CoD 5.4%; ~57/43 E/D weights. Beta is an unverified placeholder
Terminal growth rate (g)	5.0%	Approx. long-run nominal GDP growth

ACME Solar's smaller absolute capex requirement relative to its revenue base means FCFF turns positive by FY30 — a year earlier than Adani Green or NTPC Green (both FY31) — which is the key mechanical driver behind its comparatively favourable valuation outcome in Section 6.

Valuation Summary	Rs. Crores
Sum of PV of FCFF (Explicit Period, FY27–FY35)	8,917
Terminal Value (Gordon Growth, end of FY35)	1,29,855
PV of Terminal Value	53,738
Enterprise Value — Base Case	62,655

ACME Solar Holdings — FCFF Forecast, FY27–FY35 (Rs. Crores)

5. Scenario Analysis — Bear / Base / Bull

Each company's model was re-run under three scenarios to bound the valuation against the two most sensitive inputs — WACC and cost-per-MW — plus the pace of capacity addition.

- **Bear:** WACC +1 percentage point, Cost/MW +15%, capacity-addition pace $\times 0.8$
- **Base:** current model assumptions, as detailed in Section 4
- **Bull:** WACC –1 percentage point, Cost/MW –15%, capacity-addition pace $\times 1.2$

Enterprise Value across scenarios

Case	Adani Green (Rs cr)	NTPC Green (Rs cr)	ACME Solar (Rs cr)
Bear	63,706	6,304	43,893
Base	1,13,363	19,670	62,655
Bull	2,12,729	47,101	93,129

6. Final Valuation Comparison

Enterprise Value is converted to per-share intrinsic value as: Equity Value = Enterprise Value – Net Debt; Intrinsic Value per Share = Equity Value ÷ Shares Outstanding. NTPC Green's and ACME Solar's “net debt” uses total borrowings as a proxy, since a cash-netted figure was not separately disclosed in the sources used; shares outstanding are back-calculated from market cap ÷ share price across sources that showed some variation, so figures below are directional rather than precise target prices.

Market data snapshot (early August 2026)

Company	Share Price	Market Cap (Rs cr)	Shares O/S (approx.)	Net Debt (Rs cr)
Adani Green Energy	Rs 1,387.5	2,26,058	162.9 cr	91,252
NTPC Green Energy	Rs 91.3	77,000	843.4 cr	31,716 (proxy)
ACME Solar Holdings	Rs 366	26,059	71.2 cr	19,896 (proxy)

Adani Green Energy — Current Market Price: Rs 1,387.5

Case	Enterprise Value	Equity Value	Intrinsic Value/Share	Verdict
Bear	63,706	(27,546)	Negative	Overvalued
Base	1,13,363	22,111	Rs 136	Overvalued
Bull	2,12,729	1,21,477	Rs 746	Overvalued

NTPC Green Energy — Current Market Price: Rs 91.3

Case	Enterprise Value	Equity Value	Intrinsic Value/Share	Verdict
Bear	6,304	(25,412)	Negative	Overvalued
Base	19,670	(12,046)	Negative	Overvalued
Bull	47,101	15,385	Rs 18	Overvalued

ACME Solar Holdings — Current Market Price: Rs 366

Case	Enterprise Value	Equity Value	Intrinsic Value/Share	Verdict
Bear	43,893	23,997	Rs 337	Roughly Fair
Base	62,655	42,759	Rs 601	Undervalued
Bull	93,129	73,233	Rs 1,029	Undervalued

7. Hypothesis Test & Conclusion

The project's hypothesis asked whether current market valuations of renewable energy IPPs are pricing in capacity-addition and margin assumptions more aggressive than a bottom-up DCF can support. The results across all three companies, run through Bear/Base/Bull scenarios, give a clear and differentiated answer.

Adani Green Energy & NTPC Green Energy: overvalued, even in the Bull case

For both companies, intrinsic value per share falls well short of the current market price in every scenario — including the optimistic Bull case (lower WACC, cheaper capex, faster build-out). The market is pricing in assumptions more favourable than even this model's most generous case, supporting the hypothesis that these two names are trading on growth narrative and policy optimism ahead of what a bottom-up cash-flow build can justify.

ACME Solar Holdings: roughly fair to undervalued

ACME Solar shows the opposite pattern — its Base and even Bear case intrinsic values sit at or above the current market price. This is a genuinely useful finding: the overvaluation story is not uniform across the sector, and may be more specific to the largest, most-covered names (Adani Green) and high-profile PSU listings (NTPC Green) than to smaller, less-followed pure-plays like ACME Solar.

8. Key Drivers & Limitations

8.1 Key drivers behind the result

- Terminal Value dominates Enterprise Value in all three models (roughly 3x the explicit-period PV for NTPC Green) — the conclusion is most sensitive to the WACC and terminal growth (g) assumptions.
- Adani Green and NTPC Green trade at market caps that already embed the market's own view of a 50 GW / 30 GW capacity future — this model finds that even executing that plan well doesn't cash-flow-justify current prices at a defensible discount rate.
- ACME Solar's smaller capex requirement relative to its revenue base means its FCFF turns positive sooner (FY30 vs FY31 for the other two), supporting a comparatively higher intrinsic value relative to its market cap.

8.2 Limitations to state explicitly

- WACC for all three companies rests on an assumed beta (given wide disagreement across data providers for Adani Green specifically) — the conclusion's magnitude, though not its direction, would shift with a different beta choice.
- NTPC Green's and ACME Solar's Net Debt figures use total borrowings as a proxy (cash not netted out) — this modestly understates their true equity value in all cases.
- ACME Solar's cost-per-MW is a sector-average proxy, not a company-disclosed figure — the model's most significant single data gap (Section 2.3).
- Shares outstanding are back-calculated from market cap and share price across sources with some variation — precise enough for a directional conclusion, not for a precise target price.
- Capacity-addition pace is modelled as flat/equal per year during the ramp phase for all three companies, rather than the accelerating pattern seen in their actual historical build-out.

None of these limitations reverse the directional conclusion — they affect precision, not the finding that Adani Green and NTPC Green appear overvalued relative to a bottom-up DCF, while ACME Solar does not.

End of report.
